University of Birmingham, 26 March 2014

Strong thermal Leptogenesis and the

absolute neutrino mass scale

Pasquale Di Bari (University of Southampton)

The double side of Leptogenesis

Cosmology (early Universe)

Leptogenesis complements low energy neutrino experiments testing the seesaw mechanism high energy parameters

Neutrino Physics,

New Physics

In this case one would like to answer.....

...two important questions:

1. Can we get an insight on neutrino parameters from leptogenesis?

In other words: can leptogenesis provide a way to understand current neutrino parameters measurements and even predict future ones?

2. Vice-versa: can we probe leptogenesis with low energy neutrino data?

A common approach in the LHC era \Rightarrow "TeV Leptogenesis"

Is there an alternative approach based on usual high energy scale?

After all LHC has so far not found signals of new physics at the TeV scale but on the other hand a progress in our knowledge of the low energy neutrino matrix parameters got strong renewed support plus the recent BICEP2 results support the existence of a new scale $\sim 10^{16}$ GeV

Plus with the discovery of non-vanishing reactor angle guarantees the measurements of missing information in PMNS matrix in coming years.

Neutrino mixing parameters ("pre-T2K") $|v_{\alpha}\rangle = \sum U_{\alpha i} |v_{i}\rangle$

 $\theta_{13} = 3.2^{+4.5} (+9.6)$,

(Gonzalez-Garcia, Maltoni 08)

 $\theta_{23} = 43.1^{+4.4}_{-3.5} \begin{pmatrix} +10.1 \\ -8.0 \end{pmatrix}, \quad \Delta m^2_{31} = \begin{cases} -2.39 \pm 0.12 \begin{pmatrix} +0.37 \\ -0.40 \end{pmatrix} \times 10^{-3} \ \mathrm{eV}^2 \,, \\ +2.49 \pm 0.12 \begin{pmatrix} +0.39 \\ -0.36 \end{pmatrix} \times 10^{-3} \ \mathrm{eV}^2 \,, \end{cases}$

 $\delta_{CP} \in [0, 360];$

Neutrino mixing parameters				
on-vanishing		$T2K : sin^2 2\theta_{13} = 0.03 - 0.28 (90\% CL NO)$		
θ ₁₃	•	DAYA BAY: $sin^2 2\theta_{13} = 0.092 \pm 0.016 \pm 0.005$		
	•	RENO, MINOS, DOUBLE CHOO	DZ, new T2K data,	
ecent		$ \Theta_{13} = 7.7^{\circ} \div 10.2^{\circ} (95\% CL) $	(Normal Ordering)	
global		θ ₂₃ = 36.3° ÷ 40.9° (95% CL)	(Fogli, Lisi, Marron	
analyses		$\delta_{\text{bact fit}} \sim - \pi/2$	Montanino, Palazzo, Rotunno 2013)	

N

Analogous results by Ufit collaboration but $\delta_{\text{best fit}} \sim -\pi/4$ for NO

Neutrino masses: $m_1 < m_2 < m_3$

neutrino mixing data

2 possible schemes: normal or inverted

$$m_3^2 - m_2^2 = \Delta m_{\text{atm}}^2 \text{ or } \Delta m_{\text{sol}}^2 \quad m_{\text{atm}} \equiv \sqrt{\Delta m_{\text{atm}}^2 + \Delta m_{\text{sol}}^2} \simeq 0.05 \,\text{eV}$$
$$m_2^2 - m_1^2 = \Delta m_{\text{sol}}^2 \text{ or } \Delta m_{\text{atm}}^2 \quad m_{\text{sol}} \equiv \sqrt{\Delta m_{\text{sol}}^2} \simeq 0.009 \,\text{eV}$$

Tritium β decay :m_e < 2 eV (Mainz + Troitzk 95% CL)

 $\begin{array}{l} \beta\beta 0\nu: \ m_{\beta\beta} < \ 0.34 - 0.78 \ eV \\ (CUORICINO \ 95\% \ CL, \ similar \\ \ bound \ from \ Heidelberg-Moscow) \\ m_{\beta\beta} < \ 0.14 - 0.38 \ eV \\ (EXO-200 \ \ 90\% \ CL) \\ m_{\beta\beta} < \ 0.2 - 0.4 \ eV \\ (GERDA \ \ 90\% \ CL) \end{array}$

 $\begin{array}{l} \text{CMB+BAO+HO}: \Sigma \ \text{m}_{i} < 0.23 \ \text{eV} \\ \text{(Planck+high I+WMAPpol+BAO 95\%CL)} \\ \Rightarrow \ \text{m}_{1} < 0.07 \ \text{eV} \\ \text{NEW BOSS RESULTS: } \ \text{m}_{1} \sim 0.1 \text{eV} \ \text{!!} \end{array}$

Minimal scenario of Leptogenesis (Fukugita, Yanagida '86)

•Type I seesaw

$$\mathcal{L}_{\rm mass}^{\nu} = -\frac{1}{2} \left[\left(\bar{\nu}_L^c, \bar{\nu}_R \right) \left(\begin{array}{cc} 0 & \boldsymbol{m}_D^T \\ \boldsymbol{m}_D & \boldsymbol{M} \end{array} \right) \left(\begin{array}{c} \nu_L \\ \boldsymbol{\nu}_R^c \end{array} \right) \right] + h.c.$$

In the see-saw limit ($M\gg m_D$) the spectrum of mass eigenstates splits in 2 sets:

• 3 light neutrinos $u_1, \,
u_2, \,
u_3$ with masses

 $diag(m_1, m_2, m_3) = -U^{\dagger} m_D \frac{1}{M} m_D^T U^{\star}$

• 3 new heavy RH neutrinos N_1, N_2, N_3 with masses $M_3 > M_2 > M_1 \gg m_D$

•<u>Thermal production of the RH neutrinos</u> \implies T_{RH} \gtrsim M_i / (2÷10)

Seesaw parameter space

Imposing $\eta_{\rm B} = \eta_{\rm B}^{\rm CMB}$ one would like to get information on U and m_i Problem: too many parameters

(Casas, Ibarra'01)
$$m_{\nu} = -m_D \frac{1}{M} m_D^T \Leftrightarrow \Omega^T \Omega = I$$

Orthogonal parameterisation

 $\begin{bmatrix} m_D \end{bmatrix} = \begin{bmatrix} U \begin{pmatrix} \sqrt{m_1} & 0 & 0 \\ 0 & \sqrt{m_2} & 0 \\ 0 & 0 & \sqrt{m_3} \end{bmatrix} \Omega \begin{pmatrix} \sqrt{M_1} & 0 & 0 \\ 0 & \sqrt{M_2} & 0 \\ 0 & 0 & \sqrt{M_3} \end{bmatrix} \begin{bmatrix} U^{\dagger} U & = & I \\ U^{\dagger} & m_{\nu} & U^{\star} & = & -D_m \end{bmatrix}$

(in a basis where charged lepton and Majorana mass matrices are diagonal)

The 6 parameters in the orthogonal matrix Ω encode the 3 life times and the 3 total CP asymmetries of the RH neutrinos and is an invariant A parameter reduction would help and can occur if: • Iso-asymmetry surfaces $\eta_B(U, m_i; \lambda_1, ..., \lambda_9) = \eta_B^{CMB}$ (if they "close up" the

- leptogenesis bound can remove more than one parameter in this case)
 - In the asymmetry calculation $\eta_{B} = \eta_{B} (U, \mathbf{m}_{i}; \lambda_{1}, ..., \lambda_{M \leq 9})$
 - By imposing some (model dependent) conditions on m_D , one can reduce the number of parameters and arrive to a new parameterisation where

 $\Omega = \Omega (U, m_i; \lambda'_1, ..., \lambda'_{N \leq M}) \text{ and } M_i = M_i (U, m_i; \lambda'_1, ..., \lambda'_{N \leq M})$

Vanilla leptogenesis

1) Flavor composition of final leptons is neglected

$$N_{B-L}^{\text{fin}} = \sum_{i} \varepsilon_{i} \kappa_{i}^{\text{fin}} \Rightarrow \eta_{B} = a_{\text{sph}} \frac{N_{B-L}^{\text{fin}}}{N_{\gamma}^{\text{rec}}} \stackrel{\text{baryon-to}}{\underset{\text{number ratio}}{\overset{\text{-photon}}{\overset{\text{number ratio}}{\overset{\text{number ratio}}{\overset{\text{number ratio}}{\overset{\text{sphoton}}{\overset{\text{number ratio}}{\overset{\text{number ratio}}{\overset{\text{sphoton}}{\overset{\text{number ratio}}{\overset{\text{number ratio}}{\overset{\text{sphoton}}{\overset{\text{number ratio}}{\overset{\text{sphoton}}{\overset{\text{number ratio}}{\overset{\text{sphoton}}{\overset{\text{number ratio}}{\overset{\text{sphoton}}{\overset{\text{number ratio}}{\overset{\text{sphoton}}{\overset{\text{sphoton}}{\overset{\text{number ratio}}{\overset{\text{sphoton}}{\overset{\text{number ratio}}{\overset{\text{sphoton}}{\overset{\text{number ratio}}{\overset{\text{sphoton}}{\overset{\text{number ratio}}{\overset{\text{sphoton}}{\overset{\text{sphoton}}{\overset{\text{number ratio}}{\overset{\text{sphoton}}}{\overset{\text{sphoton}}{\overset{\text{sphoton}}}{\overset{shoton}}{\overset{shoton}}\overset{shoton}}{\overset{shoton}}{\overset{shoton}}\overset{shoton}}{\overset{shoton}}\overset{shoton}}{\overset{shoton}}\overset{shoton}}{\overset{shoton}}\overset{shoton}}{\overset{shoton}}\overset{shoton}}{\overset{shoton}}\overset{shoton}}{\overset{shoton}}\overset{shoton}}{\overset{shoton}}\overset{shoton}}{\overset{shoton}}\overset{shoton}}{\overset{shoton}}\overset{shoton}}{\overset{shoton}}}\overset{shoton}}{\overset{shoton}}\overset{shot$$

From the last two assumptions

$$\Rightarrow N_{B-L}^{\text{fin}} = \sum_i \varepsilon_i \,\kappa_i^{\text{fin}} \simeq \varepsilon_1 \,\kappa_1^{\text{fin}}$$

4) Barring fine-tuned mass cancellations in the seesaw

$$\varepsilon_1 \le \varepsilon_1^{\max} \simeq 10^{-6} \left(\frac{M_1}{10^{10} \,\mathrm{GeV}}\right) \frac{m_{\mathrm{atm}}}{m_1 + m_3}$$

(Davidson, Ibarra '02)

5) Efficiency factor from simple Boltzmann equations

Neutrino mass bounds in vanilla leptog.

(Davidson, Ibarra '02; Buchmüller, PDB, Plümacher '02, '03, '04; Giudice et al. '04) $\eta_B \simeq 0.01 \,\varepsilon_1(m_1, M_1, \Omega) \,\kappa_1^{\text{fin}}(K_1) \leq \eta_B^{\text{max}} = 0.01 \,\varepsilon_1^{\text{max}}(m_1, M_1) \,\kappa_1^{\text{fin}}(K_1^{\text{max}})$

No dipendence on the leptonic mixing matrix U

Strong thermal leptogenesis

The early Universe "knows" the neutrino masses ...

Beyond vanilla Leptogenesis

Degenerate limit and resonant <u>leptogenesis</u>

Vanilla Leptogenesis Non minimal Leptogenesis (in type II seesaw, non thermal,....)

> Improved Kinetic description

(momentum dependence, quantum kinetic effects,finite temperature effects,....., density matrix formalism)

Flavour Effects (heavy neutrino flavour effects, lepton flavour effects and their interplay)

Lepton flavour effects

(Abada, Davidson, Losada, Josse-Michaux, Riotto'06; Nardi, Nir, Roulet, Racker '06; Blanchet, PDB, Raffelt '06; Riotto, De Simone '06)

Flavor composition of lepton quantum states:

$$\begin{aligned} |l_1\rangle &= \sum_{\alpha} \langle l_{\alpha} | l_1 \rangle | l_{\alpha} \rangle & (\alpha = e, \mu, \tau) \\ |\bar{l}_1'\rangle &= \sum_{\alpha} \langle l_{\alpha} | \bar{l}_1' \rangle | \bar{l}_{\alpha} \rangle & \bar{P}_{1\alpha} \equiv |\langle \bar{\ell}_1' | \bar{\alpha} \rangle|^2 \end{aligned}$$

For $T \ge 10^{12} \text{ GeV} \Rightarrow \tau$ -Yukawa interactions $(\bar{l}_{L\tau} \phi f_{\tau\tau} e_{R\tau})$ are fast enough to break the coherent evolution of $|l_1\rangle$ and $|\bar{l}_1'\rangle$

 \Rightarrow they become an incoherent mixture of a τ and of a $\mu \text{+} e$ component

At T \gtrsim 10⁹ GeV then also μ - Yukawas in equilibrium \Rightarrow 3-flavor regime

Two fully flavoured regime

$$(\mathbf{a} = \mathbf{T}, \mathbf{e} + \mathbf{\mu}) \quad \begin{array}{l} P_{1\alpha} \equiv |\langle l_{\alpha} | l_{1} \rangle|^{2} = P_{1\alpha}^{0} + \Delta P_{1\alpha}/2 & \left(\sum_{\alpha} P_{1\alpha}^{0} = 1 \right) \\ \bar{P}_{1\alpha} \equiv |\langle \bar{l}_{\alpha} | \bar{l}_{1}' \rangle|^{2} = P_{1\alpha}^{0} - \Delta P_{1\alpha}/2 & \left(\sum_{\alpha} \Delta P_{1\alpha} = 0 \right) \end{array}$$

$$\Rightarrow \ \varepsilon_{1\alpha} \equiv -\frac{P_{1\alpha}\Gamma_1 - \bar{P}_{1\alpha}\bar{\Gamma}_1}{\Gamma_1 + \bar{\Gamma}_1} = \frac{P_{1\alpha}^0}{\Gamma_1 + \bar{\Gamma}_1} \varepsilon_1 + \Delta P_{1\alpha}(\Omega, U)/2$$

Classic Kinetic Equations (in their simplest form)

$$\frac{dN_{N_1}}{dz} = -D_1 \left(N_{N_1} - N_{N_1}^{eq} \right)$$

$$\frac{dN_{\Delta_{\alpha}}}{dz} = -\varepsilon_{1\alpha} \frac{dN_{N_1}}{dz} - P_{1\alpha}^0 W_1 N_{\Delta_{\alpha}}$$

$$\Rightarrow N_{B-L} = \sum_{\alpha} N_{\Delta_{\alpha}} \qquad (\Delta_{\alpha} \equiv B/3 - L_{\alpha})$$

$$\Rightarrow N_{B-L}^{fin} = \sum_{\alpha} \varepsilon_{1\alpha} \kappa_{1\alpha}^{fin} \simeq 2 \varepsilon_1 \kappa_1^{fin} + \left(\frac{\Delta P_{1\alpha}}{2} \left[\kappa_{1\alpha}^{fin} - \kappa_{1\beta}^{fin} \right] \right)$$

Upper bound on m₁

(Abada et al.' 07; Blanchet, PDB, Raffelt; Blanchet, PDB '08)

Density matrix and CTP formalism to describe the transition regimes

(De Simone, Riotto '06; Beneke, Gabrecht, Fidler, Herranen, Schwaller '10)

$$\frac{\mathrm{d}Y_{\alpha\beta}}{\mathrm{d}z} = \frac{1}{szH(z)} \left[(\gamma_D + \gamma_{\Delta L=1}) \left(\frac{Y_{N_1}}{Y_{N_1}^{\mathrm{eq}}} - 1 \right) \epsilon_{\alpha\beta} - \frac{1}{2Y_{\ell}^{\mathrm{eq}}} \left\{ \gamma_D + \gamma_{\Delta L=1}, Y \right\}_{\alpha\beta} \right] - \left[\sigma_2 \mathrm{Re}(\Lambda) + \sigma_1 |\mathrm{Im}(\Lambda)| \right] Y_{\alpha\beta}$$

Heavy neutrino flavours: the N₂-dominated scenario

(PDB '05)

If light flavour effects are neglected the asymmetry from the next-to-lightest (N_2) RH neutrinos is typically negligible:

$$N_{B-L}^{\mathrm{f},\mathrm{N}_2} = \varepsilon_2 \kappa(K_2) \, e^{-\frac{3\pi}{8} K_1} \ll N_{B-L}^{\mathrm{f},\mathrm{N}_1} = \varepsilon_1 \, \kappa(K_1)$$

...except for a special choice of $\Omega = R_{23}$ when $K_1 = m_1/m_* \ll 1$ and $\varepsilon_1 = 0$:

$$\Rightarrow \boxed{N_{B-L}^{\text{fin}} = \sum_{i} \varepsilon_{i} \,\kappa_{i}^{\text{fin}} \simeq \varepsilon_{2} \,\kappa_{2}^{\text{fin}}} \qquad \varepsilon_{2} \stackrel{<}{\sim} 10^{-6} \left(\frac{M_{2}}{10^{10} \,\text{GeV}}\right)$$

The lower bound on M_1 disappears and is replaced by a lower bound on M_2 ... that however still implies a lower bound on T_{reh} !

N₂-flavored leptogenesis

(Vives '05; Blanchet, PDB '06; Blanchet, PDB '08)

Combining together lepton and heavy neutrino flavour effects one has

$$N_{B-L}^{\rm f}(N_2) = P_{2e}^0 \,\varepsilon_2 \,\kappa(K_2) \, e^{-\frac{3\pi}{8} \,K_{1e}} + P_{2\mu}^0 \,\varepsilon_2 \,\kappa(K_2) \, e^{-\frac{3\pi}{8} \,K_{1\mu}} + P_{2\tau}^0 \,\varepsilon_2 \,\kappa(K_2) \, e^{-\frac{3\pi}{8} \,K_{1\tau}}$$

Notice that $K_1 = K_{1e} + K_{1\mu} + K_{1\tau}$

With flavor effects the domain of applicability goes much beyond the choice $\Omega = R_{23}$ The existence of the heaviest RH neutrino N₃ is necessary for the ε_{2a} not to be negligible ! More generally one has to distinguish 10 different RH neutrino mass patterns (Bertuzzo,PDB,Marzola '10)

For each pattern a specific set of Boltzmann equations has to be considered

Density matrix formalism with heavy neutrino flavours

2

(Blanchet, PDB, Jones, Marzola '11) For a thorough description of all neutrino mass patterns including transition regions and all effects (flavour projection, phantom leptogenesis,...) one needs a description in Terms of a density matrix formalism The result is a "monster" equation:

 $dN^{B-}_{\alpha\beta}$

Particularly attractive for two reasons

The conditions for the wash-out of a pre-existing asymmetry ('strong thermal leptogenesis') can be realised only within a N_2 -dominated scenario where the final asymmetry is dominantly produced in the tauon flavour

How is STL realised? - A cartoon

Strong thermal leptogenesis and the absolute neutrino mass scale

(PDB, Sophie King, Michele Re Fiorentin 2014)

Allowed regions in m_1, θ_{13} plane - $M_2 < 10^{12} \,\text{GeV}$

 $\theta_{13} = 8^{\circ} \div 10.$

Allowed regions in m_1, δ plane - $M_2 \leq 5 \cdot 10^{11} \,\text{GeV}$

SO(10)-inspired leptogenesis

(Branco et al. '02; Nezri, Orloff '02; Akhmedov, Frigerio, Smirnov '03)

Expressing the neutrino Dirac mass matrix m_D (in the basis where the Majorana mass and charged lepton mass matrices are diagonal) as:

$$m_D = V_L^{\dagger} D_{m_D} U_R$$

$$D_{m_D} = \text{diag}\{\lambda_{D1}, \lambda_{D2}, \lambda_{D3}\}$$

SO(10) inspired conditions:

 $\lambda_{D1} = \alpha_1 \, m_u \,, \, \lambda_{D2} = \alpha_2 \, m_c \,, \, \lambda_{D3} = \alpha_3 \, m_t \,, \ (\alpha_i = \mathcal{O}(1))$

$$V_L \simeq V_{CKM} \simeq I$$

From the seesaw formula one can express: $U_R = U_R (U, m_i; \alpha_i, V_L), M_i = M_i (U, m_i; \alpha_i, V_L) \Rightarrow \eta_B = \eta_B (U, m_i; \alpha_i, V_L)$

one typically obtains (barring fine-tuned 'crossing level' solutions):

 $M_1 \gg \alpha_1^2 10^5 \text{GeV}, M_2 \gg \alpha_2^2 10^{10} \text{GeV}, M_3 \gg \alpha_3^2 10^{15} \text{GeV}$

since $M_1 \ll 10^9 \text{ GeV} \Rightarrow \eta_B(N_1) \ll \eta_B^{CMB}$! \Rightarrow failure of the N₁-dominated scenario !

Crossing level solutions

(Akhmedov, Frigerio, Smirnov '03)

At the crossing the CP asymmetries undergo a resonant enhancement (Covi,Roulet,Vissani '96; Pilaftsis '98; Pilaftsis,Underwood '04; ...)

The measured η_B can be attained for a fine tuned choice of parameters: many models have made use of these solutions but as we will see there is another option

The N₂-dominated scenario rescues SO(10) inspired models

(PDB. Riotto '08)

Another way to rescue SO(10) inspired models is by considering a left-right symmetric seesaw (Abada, Hosteins, Josse-Michaux, Lavignac'08)

The model yields constraints on all low energy neutrino observables !

An improved analysis

(PDB, Marzola '11-'12)

We optimised the procedure increasing of two orders of magnitudes the number of solutions (focus on yellow points for the time being):

Why? Just to have sharper borders ? NO, two important reasons: i) statistical analysis ii) to obtain the blue green and red points

A statistical analysis

Sharp prediction on the absolute neutrino mass scales

Strong thermal SO(10) inspired leptogenesis: summary

 SO(10)-inspired leptogenesis is not only alive but it contains a subset of solutions able to satisfy quite a tight condition when flavour effects are taken into account: *independence of the initial conditions (strong thermal leptogenesis)*

ORDERING	NORMAL
θ ₁₃	≳ 2°
θ ₂₃	≲ 41°
δ	~ -45°
$m_{ee} \simeq 0.8 m_1$	~ 15 meV

- It provides an example of how (minimal) leptogenesis within a reasonable set of assumptions can yield testable predictions
- Corrections: flavour coupling, RGE effects,...
- Statistical analysis

Strong thermal SO(10)-inspired leptogenesis:

on the right track?

(PDB, Marzola '13)

If we do not plug any experimental information (mixing angles left completely free) :

Strong thermal SO(10)-inspired leptogenesis: the atmospheric mixing angle test

The allowed range for the Dirac phase gets narrower at large values of $\theta_{23}\gtrsim 35^{0}$

Conclusion

The interplay between heavy neutrino and charged lepton flavour effects introduces many new ingredients in the calculation of the final asymmetry and a density matrix formalism becomes more necessary for a correct calculation of the asymmetry

All this finds a nice application in SO(10) inspired models

Especially when the strong thermal condition is imposed, These are able to produce a scenario of leptogenesis with definite predictions on low energy neutrino parameters and with the next experimental developments all this could become exciting or easily ruled out...in any case it represents an example of how a minimal high scale leptogenesis scenario can be falsifiable

Strong thermal SO(10)-inspired leptogenesis solution

ORDERING	NORMAL
θ ₁₃	≳ 2°
θ ₂₃	≲ 41°
δ	~ -40°
$m_{ee} \simeq 0.8 m_1$	≃ 15 meV

Some insight from the decay parameters

Interplay between lepton and heavy neutrino flavour effects:

- N₂ flavoured leptogenesis
 (Vives '05: Blanchet, PDB '06: Blanchet, PDB '08)
- Phantom leptogenesis

(Antusch, PDB, King, Jones '10; Blanchet, PDB, Jones, Marzola '11)

Flavour projection
 (Barbieri, Creminelli, Stumia, Tetradis '00;

Engelhard, Grossman, Nardi, Nir '07)

• Flavour coupling (Abada, Josse Michaux '07, Antusch, PDB, King, Jones '10)

What happens to $N_{B-L}~$ at $T\sim 10^{12}~GeV?$ How does it split into a $N_{\Delta\tau}$ component and into a $N_{\Delta e^{+\mu}}$ component? One could think:

$$N_{\Delta \tau} = p_{2\tau} N_{B-L}$$

 $N_{\Delta e+\mu} = p_{2 e+\mu} N_{B-L}$

Phantom terms

However one has to consider that in the unflavoured case there are contributions to $N_{\Delta\tau}$ and $N_{\Delta e+\mu}$ that are not just proportional to N_{B-L} Remember that: $D_{D}^{0} = \Delta P_{1\alpha}$

$$\varepsilon_{1\alpha} = P_{1\alpha}^0 \,\varepsilon_1 + \frac{\Delta P_{1\alpha}}{2}$$

Assume an initial thermal N₂-abundance at T~ M₂ >> 10¹² GeV

Phantom Leptogenesis

(Antusch, PDB, King, Jones '10)

Let us then consider a situation where K₂>> 1 so that at the end of the N₂ washout the total asymmetry is negligible: 1) T ~ M₂ : unflavoured regime

$$egin{array}{c|c|c|c|c|} \hline au & {f e}^+\mu \ \hline \overline au & {f e}^+\mu \end{array} & \Rightarrow & N^{T\sim M_2}_{B-L}\simeq 0 \;! \end{array}$$

2) 10^{12} GeV \gtrsim T >> M₁ :decoherence \implies 2 flavoured regime

 $N_{B-L}^{T \sim M_2} = N_{\Delta au}^{T \sim M_2} + N_{\Delta_{e+\mu}}^{T \sim M_2} \simeq 0 !$ 3) T $\simeq M_1$: asymmetric washout from lightest RH neutrino Assume K_{1T} $\lesssim 1$ and K_{1e+µ} >> 1 $N_{B-L}^{f} \simeq N_{\Delta_{ au}}^{T \sim M_2} !$

The N_1 wash-out un-reveal the phantom term and effectively it creates a N_{B-L} asymmetry.

Phantom Leptogenesis within a density matrix formalism

(Blanchet, PDB, Marzola, Jones '11-12')

In a picture where the gauge interactions are neglected the lepton and anti-leptons density matrices can be written as:

There is a recent update (see 1112.4528 v2 to appear in JCAP)

Because of the presence of gauge interactions, the difference

of flavour composition between lepton and anti-leptons is measured and this induces a wash-ou the phantom terms from Yukawa interactions though with halved wash-out rate compared to to one acting on the total asymmetry and in the end:

$$N_{\tau\tau}^{B-L,f} \simeq p_{2\tau}^0 N_{B-L}^f - \frac{\Delta p_{2\tau}}{2} \kappa(K_2/2),$$

Flavour projection

(Engelhard, Nir, Nardi '08 , Bertuzzo,PDB,Marzola '10) Assume M_{i+1} ≥ 3M_i (i=1,2)

The heavy neutrino flavour basis cannot be orthonormal 2 otherwise the CP asymmetries would vanish: this complicates the calculation of the final asymmetry $p_{ij} = |\langle \ell_i | \ell_j \rangle|^2 \qquad p_{ij} = \frac{\left| (m_D^{\dagger} m_D)_{ij} \right|^2}{(m_D^{\dagger} m_D)_{ij} (m_D^{\dagger} m_D)_{ij}}.$ 10c (1-P12) $N_{B-L}^{(N_2)}(T \ll M_1) = N_{\Delta_1}^{(N_2)}(T \ll M_1) + N_{\Delta_{1\perp}}^{(N_2)}(T \ll M_1)$ Component from heavier RH neutrinos Contribution from heavier RH parallel to l1 and washed-out by N1 neutrinos orthogonal to l₁ and escaping inverse decays N₁ wash-out $N^{(N_2)}_{\Delta_1}(T \ll M_1) = p_{12} e^{-\frac{3\pi}{8}K_1} N^{(N_2)}_{B-L}(T \sim M_2)$

2 RH neutrino scenario revisited

(King 2000;Frampton,Yanagida,Glashow '01,Ibarra, Ross 2003;Antusch, PDB,Jones,King '11) In the 2 RH neutrino scenario the N₂ production has been so far considered to be safely negligible because ε_{2α} were supposed to be strongly suppressed and very strong N₁ wash-out. But taking into account:

- the N_2 asymmetry N_1 -orthogonal component
- an additional unsuppressed term to $\epsilon_{2\alpha}$

New allowed N₂ dominated regions appear

dominated neutrino mass models realized in some grandunified models

Flavour projection

(Engelhard, Nir, Nardi '08 , Bertuzzo, PDB, Marzola '10)

The heavy neutrino flavour basis cannot be orthonormal otherwise the CP asymmetries would vanish: this complicates the calculation of the final asymmetry μ $p_{ij} = |\langle \ell_i | \ell_j \rangle|^2 \qquad p_{ij} = \frac{\left| (m_D^{\dagger} m_D)_{ij} \right|^2}{(m_D^{\dagger} m_D)_{ii} (m_D^{\dagger} m_D)_{ij}}.$ 615 $N_{\rm B\,i\,\,L}^{\rm (N_{\,2})}(T\,\dot{\epsilon}\ M_{\rm 1}) = N_{\rm c_{\,1}}^{\rm (N_{\,2})}(T\,\dot{\epsilon}\ M_{\rm 1}) + N_{\rm c_{\,1?}}^{\rm (N_{\,2})}(T\,\dot{\epsilon}$ M_1) Component from heavier RH neutrinos Contribution from heavier RH **parallel** to I_1 and washed-out by N_1 neutrinos orthogonal to I_1 and escaping inverse decays N₁ wash-out $N_{\rm c_1}^{\rm (N_2)}(T \doteq M_{\rm 1}) = p_{\rm 12} e^{{\rm i} -\frac{3\,{\rm M}}{8}\,{\rm K_1}} N_{\rm B\,{\rm i}\,{\rm L}}^{\rm (N_2)}(T \gg M_{\rm 2})$

Phantom Leptogenesis

(Antusch, PDB, King, Jones '10)

Consider this situation

 M_2 $\sim 10^{12} \text{ GeV}$ M_1 $\sim 10^9 \text{ GeV}$ $N_1 - \text{washout in the 2 fl. regime}$

What happens to N_{B-L} at T ~ 10^{12} GeV? How does it split into a $N_{\Delta\tau}$ component and into a $N_{\Delta e^{+\mu}}$ component? One could think:

$$N_{\Delta \tau} = p_{2\tau} N_{B-L}$$

 $N_{\Delta e^{+}\mu} = p_{2 e^{+}\mu} N_{B-L}$

Phantom terms

However one has to consider that in the unflavoured case there are contributions to $N_{\Delta \tau}$ and $N_{\Delta e^+\mu}$ that are not just proportional to N_{B-L} Remember that: $\varepsilon_{1\alpha} = P_{1\alpha}^0 \varepsilon_1 + \frac{\Delta P_{1\alpha}}{2}$

Assume an initial thermal N_2 -abundance at T~ M_2 >> 10^{12} GeV

Phantom Leptogenesis

(Antusch, PDB, King, Jones '10)

Let us then consider a situation where $K_2 >> 1$ so that at the end of the N₂ washout the total asymmetry is negligible:

1) $T \sim M_2$: unflavoured regime

$$N_{\rm B\,i\,L}^{\rm T\,\,*\,\,M_{\,2}}$$
 ' 0!

2) 10¹² GeV X T >> M₁: decoherence X 2 flavoured regime N^T_{B i L} = N^T_{c i} M₂ + N^T_{c e+1} 0 !
3) T X M₁: asymmetric washout from lightest RH neutrino Assume K_{1T} X 1 and K_{1e+µ} >> 1 N^f_{B i L} N^T_{c i} M₂ !
The N₁ wash-out un-reveal the phantom term and effectively it creates a N_{B-L} asymmetry. Fully confirmed within a density matrix formalism (Blanchet, PDB, Marzola, Jones '11)

Remarks on phantom Leptogenesis

We assumed an initial N_2 thermal abundance but if we were assuming An initial vanishing N_2 abundance the phantom terms were just zero !

$$N_{ extsf{c}_{\dot{c}}}^{ extsf{phantom}} = rac{ extsf{c} \ extsf{p}_{2\dot{c}}}{2} N_{ extsf{N}_{2}}^{ extsf{in}}$$

The reason is that if one starts from a vanishing abundance during the N₂ production one creates a contribution to the phantom term by inverse decays with opposite sign and exactly cancelling with what is created in the decays

In conclusionphantom leptogenesis introduces additional strong dependence on the initial conditions

NOTE: in strong thermal leptogenesis phantom terms are also washed out: full independence of the initial conditions!

Phantom terms cannot contribute to the final asymmetry in N₁ leptogenesis but (canceling) flavoured asymmetries can be much bigger than the baryon asymmetry and have implications in active-sterile neutrino oscillations

$I \leq V_L \leq V_{CKM}$

INVERTED ORDERING

 $\alpha_2 = 5$ $\alpha_2 = 4$ $\alpha_2 = 1.5$

No link between the sign of the asymmetry and \mathbf{J}_{CP}

(PDB, Marzola)

It is confirmed that there is no link between the matter-antimatter asymmetry and CP violation in neutrino mixing......for the yellow points

WHAT ARE THE NON-YELLOW POINTS?

Link between the sign of J_{CP} and the sign of the asymmetry $\eta_{B} = \eta^{CMB}_{B}$ $\eta_{B} = -\eta^{CMB}_{B}$
